Greach

1. Code sample and notes

The code for this presentation is available at https://github.com/danhyun/2017-greach-rapid-ratpack-groovy.

These notes are also available in PDF format.

2. Goal

- Produce a REST API in Groovy to manage Todos.
- Pass specifications @ todobackend.com
- Plug into a Todo Frontend app

3. Tools

- Ratpack (Web server)
- Gradle (Build tool)

4. What is Ratpack?

Ratpack is a set of developer friendly, reactive, asynchronous, non-blocking Java 8 libraries that facilitate rapid web application development.

- Lightweight
  - No SDK binaries download
  - No intermediary code generation
- Doesn’t implement Servlet Specification.
  - Uses Netty for underlying network programming
  - No Servlets
  - No Servlet Container
- Not "Fullstack" not MVC; Functionality is provided via "modules"
  - Core (HTTP/Execution)
  - Sessions/Auth Pac4j
  - Database (HikariCP)
  - RxJava/Hystrix
  - Templating (Groovy’s MarkupTemplateEngine, Handlebars, Thymeleaf
  - Dependency Injection (Guice/Spring Boot)
- First class testing support
  - Test framework agnostic fixtures that let you test around every feature of Ratpack

5. Hola mundo

Getting started in Ratpack is a non-event. You may be accustomed to jumping through hoops to get a new web project started. To demonstrate Ratpack’s low effort project initialization, consider the following Groovy script.

example-01-groovy-script/src/main/groovy/ratpack.groovy

```
@Grab('io.ratpack:ratpack-groovy:1.4.5') ①

import static ratpack.groovy.Groovy.ratpack

ratpack { ②
  handlers { ③
    get { ④
      render 'Hola mundo' ⑤
    }
  }
}
```

① Use `@Grab` to pull `ratpack-groovy` artifact

② Invoke `ratpack` method to define server

③ Use `handlers` to declare the `Chain` of our application

④ Define a `Handler` bound to `HTTP GET /`

⑤ Render 'Hola mundo' to the client

That's really all that's required to get started!

We're now ready to start our application. We'll invoke the run task then navigate to `localhost:5050`

```
$ groovy example-01-groovy-script/src/main/groovy/ratpack.groovy

$ curl -s localhost:5050
Hola mundo
```

5.1. Live reload

When prototyping Ratpack apps in a Groovy script, you can change the script while the application and see your changes reflected in real time! There's no need to re-run the Groovy script.

```
$ groovy example-01-groovy-script/src/main/groovy/ratpack.groovy

$ curl -s localhost:5050
Hola mundo

# modify ratpack.groovy to
# @Grab('io.ratpack:ratpack-groovy:1.4.5')
#
# import static ratpack.groovy.Groovy.ratpack
#
# ratpack {
#   handlers {
#     get {
#       render 'Hola Greach!'
#     }
#   }
# }

$ curl localhost:5050
Hola Greach!
```

6. Handlers

Handlers are where request processing logic is provided. A `Handler` is a functional interface defined as `void handle(Context context)` and can be easily expressed as a Groovy `Closure`. The context is a registry that provides access to a map-like data-structure that can be populated and queried. Request and response objects are accessible via the `Handler`.

6.1. Request Response Interaction

As an implementation detail of the TodoBackend application, we need to set CORS headers on each response.

Setting headers on the response

example-02-handlers/src/main/groovy/ratpack.groovy

```
@Grab('io.ratpack:ratpack-groovy:1.4.5')

import static ratpack.groovy.Groovy.ratpack
import ratpack.http.MutableHeaders

ratpack {
  handlers {
    get {
      MutableHeaders headers = response.headers ①
      headers.set('Access-Control-Allow-Origin', '*') ②
      headers.set('Access-Control-Allow-Headers', 'x-requested-with, origin, content-
type, accept') ②
      render 'Hola Greach 2017!'
    }
  }
}
```

① Access the response's headers from the `Context`

② Add some headers for implementing CORS functionality

ratpack Demo

```
$ groovy example-02-handlers/src/main/groovy/ratpack.groovy ①

$ curl -v localhost:5050
* Rebuilt URL to: localhost:5050/
* timeout on name lookup is not supported
*   Trying ::1...
* Connected to localhost (::1) port 5050 (#0)
> GET / HTTP/1.1
> Host: localhost:5050
> User-Agent: curl/7.45.0
> Accept: */*
>
< HTTP/1.1 200 OK
< Access-Control-Allow-Origin: * ②
< Access-Control-Allow-Headers: x-requested-with, origin, content-type, accept ②
< content-type: text/plain;charset=UTF-8
< content-length: 20
< connection: keep-alive
<
Hola Greach 2017!
```

① Invoke our Ratpack Groovy script

② Issue curl and inspect response headers to verify that our CORS headers are added

6.2. Organization

Because our REST implementation requires that CORS is enabled, the `Access-Control-Allow-Origin` and `Access-Control-Allow-Headers` headers need to be set on every response. However, setting these headers in each `Handler` is tedious and error prone. Luckily `Handler` s are designed to be composable units of request processing. Handlers are composed in a logical manner via the `Chain`. Handlers can either send a response or delegate further request processing to the next `Handler` in the `Chain`. Handlers signal delegation via `Context#next`.

We'll start our refactoring by extracting the CORS setting logic to its own handler.

example-02-handlers/src/main/groovy/ratpack2.groovy

```
@Grab('io.ratpack:ratpack-groovy:1.4.5')

import static ratpack.groovy.Groovy.ratpack
import ratpack.http.MutableHeaders

ratpack {
  handlers {
    all { ①
      MutableHeaders headers = response.headers
      headers.set('Access-Control-Allow-Origin', '*')
      headers.set('Access-Control-Allow-Headers', 'x-requested-with, origin, content-
type, accept')
      next() ②
    }
    get {
      render 'Hola Greach 2017!'
    }
  }
}
```

① Declare a new handler to handle all incoming requests regardless of method or path

② Delegate processing to the next `Handler` in the chain

We can curl the application to make sure that the headers are indeed being set for each request.

ratpack2 Demo

```
$ groovy example-02-handlers/src/main/groovy/ratpack2.groovy ①

$ curl -v localhost:5050/
* timeout on name lookup is not supported
*   Trying ::1...
* Connected to localhost (::1) port 5050 (#0)
> GET / HTTP/1.1
> Host: localhost:5050
> User-Agent: curl/7.45.0
> Accept: */*
```

```
>
< HTTP/1.1 200 OK
< Access-Control-Allow-Origin: * ②
< Access-Control-Allow-Headers: x-requested-with, origin, content-type, accept ②
< content-type: text/plain;charset=UTF-8
< content-length: 20
< connection: keep-alive
<
Hola Greach 2017!

$ curl -v localhost:5050/no-such-path
* timeout on name lookup is not supported
*   Trying ::1...
* Connected to localhost (::1) port 5050 (#0)
> GET /no-such-path HTTP/1.1
> Host: localhost:5050
> User-Agent: curl/7.45.0
> Accept: */*
>
< HTTP/1.1 404 Not Found
< Access-Control-Allow-Origin: * ③
< Access-Control-Allow-Headers: x-requested-with, origin, content-type, accept ③
< content-type: text/plain
< content-length: 16
< connection: keep-alive
<
Client error 404

$ curl -X POST -v localhost:5050/
* timeout on name lookup is not supported
*   Trying ::1...
* Connected to localhost (::1) port 5050 (#0)
> POST / HTTP/1.1
> Host: localhost:5050
> User-Agent: curl/7.45.0
> Accept: */*
>
< HTTP/1.1 405 Method Not Allowed
< Access-Control-Allow-Origin: * ④
< Access-Control-Allow-Headers: x-requested-with, origin, content-type, accept ④
< content-type: text/plain
< content-length: 16
< connection: keep-alive
<
Client error 405
```

① Run `ratpack2.groovy` script

② Verify that CORS headers were added to `GET /` endpoint

③ Verify that CORS headers were added to undefined `GET /no-such-path` endpoint

④

Verify that CORS headers were added to unsupported `POST /` endpoint

6.3. Standalone Handlers

As you can imagine, the number of handlers in your chain can quickly grow. Ratpack provides ways to evolve your code base as your handlers and chains grow.

The idea is to migrate handling logic to discrete classes or groups of classes in order to keep your codebase readable and maintainable.

example-02-handlers/src/main/groovy/ratpack3.groovy

```
@Grab('io.ratpack:ratpack-groovy:1.4.5')

import static ratpack.groovy.Groovy.ratpack
import ratpack.http.MutableHeaders

import groovy.transform.CompileStatic
import ratpack.groovy.handling.GroovyContext
import ratpack.groovy.handling.GroovyHandler

@CompileStatic
class CORSHandler extends GroovyHandler { ①
  @Override
  protected void handle(GroovyContext context) {
    MutableHeaders headers = context.response.headers
    headers.set('Access-Control-Allow-Origin', '*')
    headers.set('Access-Control-Allow-Headers', 'x-requested-with, origin, content-
type, accept')
    context.next()
  }
}

ratpack {
  handlers {
    all(new CORSHandler()) ②
    get {
      render 'Hola Greach 2017!'
    }
  }
}
```

① Extract our CORS handling logic to its own class

② Add the newly migrated `CORSHandler` to our Chain

7. Migrating to Gradle

As your prototype starts to evolve into a more serious application, you will want to start using a serious build tool like Gradle. We'll start by creating our `build.gradle` file.

example-03-gradle/example-03-gradle.gradle

```
plugins { ①
  id 'io.ratpack.ratpack-groovy' version '1.4.5' ②
}

repositories {
  jcenter() ③
}
```

① Make use of the incubating `plugins` DSL feature

② Tell Gradle to use the Ratpack Groovy Gradle plugin

③ Tell Gradle to look for artifacts in Bintray JCenter

We'll also move our `ratpack.groovy` file to `$projectDir/src/ratpack/ratpack.groovy` and put `CORSHandler.groovy` in the typical `$projectDir/src/main/groovy` location for regular Groovy classes. The `$projectDir/src/ratpack` directory is a convention used by Ratpack as a common directory for holding configuration files, templates, static assets and your main Ratpack application script.

Once everything is in its place you should see a directory structure similar to this:

Directory structure after migrating to Gradle

```
example-03-gradle
 │    example-03-gradle.gradle
 │
 └───────src
     ├───────main
     │    └───────groovy
     │            CORSHandler.groovy
     │
     └───────ratpack
             ratpack.groovy
```

7.1. Why not Maven?

Because Ratpack is simply a set of Java libraries, all that is required to build Ratpack applications are the Ratpack jar files and `javac`. You are free to use any build tool: Ant + Ivy, Maven, Gradle, etc.

Ratpack has first-class Gradle support provided via Ratpack's Gradle plugin. It allows for easy dependency management (keeps versions of modules in sync) and hooks into Gradle's continuous functionality.

Can you create a Maven `pom.xml` file from memory? I certainly cannot. I can create a `build.gradle` file from memory though.

build.gradle

```
plugins { ①
  id 'io.ratpack.ratpack-groovy' version '1.4.5' ②
}

repositories {
  jcenter() ③
}
```

① Make use of Gradle's incubating Plugins DSL (since Gradle 2.1)

② Declare and apply Ratpack's Gradle plugin for Groovy, provides `ratpack-core` module

③ Tell Gradle to pull dependencies from Bintray JCenter

Gradle has a number of out of the box features that make it superior to Maven however the one I will highlight here is the Gradle Wrapper.

The Gradle Wrapper is a set of files that enables developer on a project to use the same exact version of Gradle. This is a best practice when it comes to working with Gradle. Because Gradle is such a well maintained build tool, there are many updates. The Gradle Wrapper goes a long way towards preventing "works on my machine" syndrome. Wrapper scripts are available in `bash` and `bat` formats. Because the scripts are typically a part of the project, you don't *need* to install Gradle to use it, just use the `gradlew` scripts. At some point however, someone somewhere needs to install gradle. I recommend installing http://sdkman.io to manage Gradle installations. To generate the wrapper, invoke `gradle wrapper` from the command line.

When generating scripts from Windows, make sure to `chmod +x gradlew` so that your *nix/Mac co-workers and CI server can execute the wrapper script.

7.2. Launching via Gradle

Launching our Ratpack application is straightforward thanks to the Ratpack Gradle plugin.

Simply execute the `:run` task to launch your Ratpack application:

```
$ ./gradlew :example-03-gradle:run

$ curl -s localhost:5050
Hola mundo
```

7.3. Continuous Mode

If you add `-t` or `--continuous` to the task execution, Gradle's continuous mode will be invoked. Gradle's continuous mode monitors source code and reruns the specified task.

Continuous mode cannot currently respond to changes in Gradle build scripts, only in source code or resources.

```
$ ./gradlew :example-03-gradle:run -t

$ curl -s localhost:5050 | cat
Hola mundo!

# modify ratpack.groovy

Change detected, executing build...

:example-03-gradle:compileJava UP-TO-DATE
:example-03-gradle:compileGroovy UP-TO-DATE
:example-03-gradle:processResources
:example-03-gradle:classes
:example-03-gradle:configureRun
:example-03-gradle:run
Ratpack started (development) for http://localhost:5050

BUILD SUCCESSFUL

Total time: 0.374 secs

$ curl -s localhost:5050
Hola Greach 2017!
```

8. Database

In order to provide persistence to our REST application we'll make use of a number of libraries. We'll be using an in-memory h2 database as our main datasource, HikariCP — a very fast JDBC connection pool library, and jOOQ as our primary means of querying the datasource.

The Gradle build file should look something like this:

8.1. Updating Build Script

example-04-database/example-04-database.gradle

```
buildscript {
  repositories {
    jcenter()
  }
  dependencies {
    classpath 'com.h2database:h2:1.4.186'   ①
    classpath 'org.jooq:jooq-codegen:3.8.1' ②
  }
}

plugins {
  id 'io.ratpack.ratpack-groovy' version '1.4.5'
}

repositories {
  jcenter()
}

dependencies {
  compile ratpack.dependency('hikari') ③
  compile 'com.h2database:h2:1.4.186' ④
  compile 'org.jooq:jooq:3.8.1' ⑤
}
```

① Add h2 as dependency to buildscript

② Add `jooq-codegen` as dependency to buildscript

③ Add compile time dependency on `ratpack-hikari`

④ Add compile time dependency on `h2`

⑤ Add compile time dependency on `jooq`

We needed to introduce a `buildscript` closure to the build script in order to provide these libraries during task execution. The reason we couldn't use the `plugins` DSL is because these h2 and jOOQ libraries are not published as Gradle plugins in the Gradle plugin portal. We'll add a task to our Gradle build script that enables us to generate the classes that reflect our schema.

If you notice `(3)` uses a distinct method to include the `ratpack-hikari` module. The `ratpack.dependency` method is provided from the Ratpack Gradle plugin and it allows you to specify the module name in place of the full Group Artifact Version coordinates. `ratpack.dependency('hikari')` in this context is equivalent to `'io.ratpack:ratpack-hikari:1.4.5'`.

8.2. Defining the Schema

Our domain consists of a single entity, the Todo. We will add this initial sql script to our project's resources directory.

example-04-database/src/main/resources/init.sql

```
DROP TABLE IF EXISTS todo;
CREATE TABLE todo (
  `id` bigint auto_increment primary key,
  `title` varchar(256),
  `completed` bool default false,
  `order` int default null
)
```

8.3. Generating jOOQ classes

We'll make use of a fluent Java API provided by the `jooq-codegen` library, made available previously in the `buildscript` closure. We'll use this API and h2 to tell jOOQ how to connect to our datasource, which schemata/tables to include and where to place the generated files.

example-04-database/example-04-database.gradle

```
task jooqCodegen {
  doLast {
    String init = "$projectDir/src/main/resources/init.sql".replaceAll('\\\\', '/') ①
    Configuration configuration = new Configuration()
      .withJdbc(new Jdbc()
      .withDriver("org.h2.Driver") ②
      .withUrl("jdbc:h2:mem:todo;INIT=RUNSCRIPT FROM '$init'") ③
    )
      .withGenerator(new Generator()
        .withDatabase(new Database()
          .withName("org.jooq.util.h2.H2Database")
          .withIncludes(".*")
          .withExcludes("")
          .withInputSchema("PUBLIC")
        )
      .withTarget(new Target()
        .withDirectory("$projectDir/src/main/groovy") ④
        .withPackageName("jooq"))) ⑤
    GenerationTool.generate(configuration)
  }
}
```

① Grab our `init` script from the project, clean up path separator if on Windows

② Configure jOOQ code generation to use h2 Driver

③ Configure h2 URL to run the init script

④ Specify the target directory

⑤ Specify name of parent package to contain generated classes relative to target directory

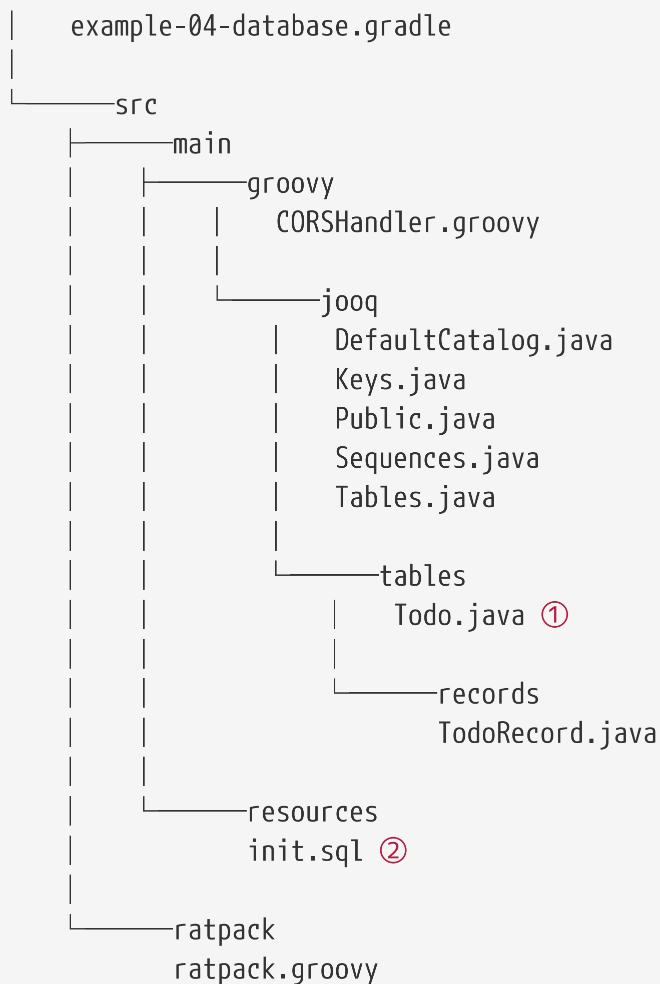
Once this task is added, run it from the command line:

```
$ ./gradlew :example-04-database:jooqCodegen
:example-04-database:jooqCodegen

BUILD SUCCESSFUL

Total time: 0.985 secs
```

You should see the generated files in your project now:



```
│   example-04-database.gradle
│
└───────src
    ├───────main
    │    ├───────groovy
    │    │    │   CORSHandler.groovy
    │    │    │
    │    │    └───────jooq
    │    │        │   DefaultCatalog.java
    │    │        │   Keys.java
    │    │        │   Public.java
    │    │        │   Sequences.java
    │    │        │   Tables.java
    │    │        │
    │    │        └───────tables
    │    │            │   Todo.java ①
    │    │            │
    │    │            └───────records
    │    │                  TodoRecord.java
    │    │
    │    └───────resources
    │             init.sql ②
    │
    └───────ratpack
             ratpack.groovy
```

① `Todo` represents our table from our `init.sql`

② Our TODO schema definition

8.4. Integration

Integrating the new datasource into our REST application is fairly straightforward. We need to register the H2 datasource and the Ratpack HikariCP module with Ratpack's registry.

example-04-database/src/ratpack/ratpack.groovy

```
import static ratpack.groovy.Groovy.ratpack
import ratpack.hikari.HikariModule

ratpack {
  bindings { ①
    module(HikariModule) { config -> ②
      config.dataSourceClassName = 'org.h2.jdbcx.JdbcDataSource' ③
      config.addDataSourceProperty('URL', "jdbc:h2:mem:tood;INIT=RUNSCRIPT FROM
'classpath:/init.sql'") ③
    }
  }
  handlers {
    all(new CORSHandler())
    get {
      render 'Hola mundo!'
    }
  }
}
```

① Make use of `bindings` method to provide objects to be registered into the `Registry`

② Add the `HikariModule` provided by `ratpack.dependency('hikari')`

③ Configure the `HikariModule` with our H2 connection information

Next we'll add a handler to perform some SQL query and send the result to the client.

example-04-database/src/ratpack/ratpack2.groovy

```
get('blocking') {
  DataSource ds = get(DataSource) ①
  DSLContext dsl = DSL.using(ds, SQLDialect.H2) ②
  def todos = dsl.select().from(Todo.TODO).fetchMaps() ③
  render(Jackson.json(todos)) ④
}
```

① Retrieve the `DataSource` registered from `HikariModule` from the `Context`

② Create a `DSLContext` jOOQ object for querying the datasource

③ Issue a `SELECT * FROM TODO;` and marshal to List of Maps

④ Return results as JSON to the user

We are now set to query from a datasource and send results as JSON to the client.

Do not deploy this code! Our implementation is very naive and will cause very poor performance in production. We'll continue in the next section in how to improve our implementation.

9. Asynchronous Programming

At this point we should remember that Ratpack is a non-blocking and asynchronous framework. This has implications in how you code your `Handler` logic. If you are performing any kind of blocking I/O or any kind of computationally expensive operation, you'll need to tap into Ratpack's Blocking executor in order to let the main request processing thread continue processing requests. If you fail to use the Blocking executor you will start to observe performance degradation.

9.1. Blocking.get()

In the previous example we were making a blocking JDBC call, preventing the request processing thread of execution from tending to any other incoming requests. Ratpack provides a mechanism that allows you to create promises that will be executed on a separate thread pool. We will use this Blocking mechanism to represent a bit of work that should not be performed on the request taking thread. Promises are **l-a-z-y**. Promises in Ratpack are not executed unless they are subscribed via `Promise#then`. Promises will **always** be resolved in the order in which they were declared. Ratpack promise execution is deterministic. There is a detailed set of blog articles by @ldaley, the project lead of Ratpack that explains this.

Let's rewrite the previous example using the `Blocking` mechanism.

example-05-async/src/ratpack/ratpack.groovy

```
get('blocking') {
  DataSource ds = get(DataSource)
  DSLContext dsl = DSL.using(ds, SQLDialect.H2)
  def select = dsl.select().from(Todo.TODO)
  Promise promise = Blocking.get { ①
    select.fetchMaps()
  }
  promise.then { todos -> ②
    render(Jackson.json(todos))
  }
}
```

① Use `Blocking.get` to wrap the blocking JDBC call

② Resolve the promise and render the JSON serialized representation to the user

It should be noted that the strongly typed queries can be separated from their actual execution in jOOQ. If the methods contain names like `fetch*`, `refresh`, `execute`, `store`, etc these are most likely the actual blocking JDBC call.

9.2. Code cleanup

At this point we'll take the time to create a dedicated class that handles CRUD operations for the `TODO` table.

First we'll create a `TodoModel` that represents our `TODO` domain model.

example-05-async/src/main/groovy/TodoModel.groovy

```groovy
import com.fasterxml.jackson.annotation.JsonCreator
import com.fasterxml.jackson.annotation.JsonProperty
import groovy.transform.CompileStatic

@CompileStatic
class TodoModel {
  final Long id
  final String title
  final boolean completed
  final Integer order
  private final String baseUrl

  @JsonCreator
  TodoModel(@JsonProperty("id") Long id,
            @JsonProperty("title") String title,
            @JsonProperty("completed") boolean completed,
            @JsonProperty("order") Integer order) {
    this(id, title, completed, order, null)
  }

  TodoModel(Long id, String title, boolean completed, Integer order, String baseUrl) {
    this.id = id
    this.title = title
    this.completed = completed
    this.order = order
    this.baseUrl = baseUrl
  }

  TodoModel baseUrl(String baseUrl) {
    return new TodoModel(id, title, completed, order, baseUrl)
  }

  String getUrl() {
    return "$baseUrl/$id"
  }

}
```

Next we'll create a `TodoRepository` for performing CRUD operations on this `TodoModel`

Let's start by migrating the `SELECT * FROM TODO` from the previous `Handler`

example-05-async/src/main/groovy/TodoRepository.groovy

```
private final DSLContext create;

TodoRepository(DataSource ds) {
  this.create = DSL.using(ds, SQLDialect.H2)
}

Promise<List<TodoModel>> getAll() {
  SelectJoinStep all = create.select().from(TODO)
  return Blocking.get { all.fetchInto(TodoModel.class) }
}
```

We will now create a `TodoModule` that will provide this `TodoRepository` to the Ratpack registry.

example-05-async/src/main/groovy/TodoModule.groovy

```
import com.google.inject.AbstractModule
import com.google.inject.Provides
import groovy.transform.CompileStatic

import javax.inject.Singleton
import javax.sql.DataSource

@CompileStatic
class TodoModule extends AbstractModule {
  @Override
  protected void configure() {}

  @Provides
  @Singleton
  TodoRepository todoRepository(DataSource ds) {
    return new TodoRepository(ds) ①
  }
}
```

① We're defining the `TodoRepository` as a singleton

Next we'll register this `TodoModule` with Ratpack

example-05-async/src/ratpack/ratpack.groovy

```
module(TodoModule)
```

Finally we'll update the `Handler` to make use of the `TodoRepository`

example-05-async/src/ratpack/ratpack2.groovy

```
get('blocking') {
  TodoRepository repository = get(TodoRepository.class) ①
  Promise<List<TodoModel>> todos = repository.getAll() ②
  todos.then{ t -> render(Jackson.json(t)) } ③
}
```

For style points use method references.

example-05-async/src/ratpack/ratpack3.groovy

```
get('blocking') {
  TodoRepository repository = get(TodoRepository.class) ①
  repository.getAll()
    .map(Jackson.&json)
    .then(context.&render)
}
```

In Groovy, you can provide your Handler closure with types from the Registry and Ratpack will set them for you.

example-05-async/src/ratpack/ratpack4.groovy

```
get('blocking') { TodoRepository repository -> ①
  repository.getAll()
    .map(Jackson.&json)
    .then(context.&render)
}
```

① Specify `TodoRepository` as a parameter to have Ratpack supply this registered object for you

Doesn't that look lovely?

9.3. Putting it all together

Here is what the `TodoRepository`, `TodoModule` and `App` should look like at this point:

example-05-async/src/main/groovy/TodoRepository2.groovy

```
import groovy.transform.CompileStatic
import jooq.tables.records.TodoRecord
import org.jooq.*
import org.jooq.impl.DSL
import ratpack.exec.Blocking
import ratpack.exec.Operation
import ratpack.exec.Promise
```

```
import javax.sql.DataSource

import static jooq.tables.Todo.TODO

@CompileStatic
class TodoRepository2 {
  private final DSLContext create

  TodoRepository2(DataSource ds) {
    this.create = DSL.using(ds, SQLDialect.H2)
  }

  Promise<List<TodoModel>> getAll() {
    SelectJoinStep all = create.select().from(TODO)
    return Blocking.get { all.fetchInto(TodoModel.class) }
  }

  Promise<TodoModel> getById(Long id) {
    SelectConditionStep where = create.select().from(TODO).where(TODO.ID.equal(id))
    return Blocking.get { where.fetchOne().into(TodoModel.class) }
  }

  Promise<TodoModel> add(TodoModel todo) {
    TodoRecord record = create.newRecord(TODO, todo)
    return Blocking.op(record.&store)
      .next(Blocking.op(record.&refresh))
      .map { record.into(TodoModel.class) }
  }

  Promise<TodoModel> update(Map<String, Object> todo) {
    TodoRecord record = create.newRecord(TODO, todo)
    return Blocking.op { create.executeUpdate(record) }
      .next(Blocking.op(record.&refresh))
      .map { record.into(TodoModel.class) }
  }

  Operation delete(Long id) {
    DeleteConditionStep<TodoRecord> deleteWhereId = create.deleteFrom(TODO).where(
TODO.ID.equal(id))
    return Blocking.op(deleteWhereId.&execute)
  }

  Operation deleteAll() {
    DeleteWhereStep<TodoRecord> delete = create.deleteFrom(TODO)
    return Blocking.op(delete.&execute)
  }
}
```

example-05-async/src/main/groovy/TodoModule2.groovy

```groovy
import com.google.inject.AbstractModule
import com.google.inject.Provides
import groovy.transform.CompileStatic

import javax.inject.Singleton
import javax.sql.DataSource

@CompileStatic
class TodoModule2 extends AbstractModule {
  @Override
  protected void configure() {}

  @Provides
  @Singleton
  TodoRepository todoRepository(DataSource ds) {
    return new TodoRepository(ds)
  }
}
```

example-05-async/src/ratpack/ratpack5.groovy

```groovy
import ratpack.hikari.HikariModule
import ratpack.jackson.Jackson

import static ratpack.groovy.Groovy.ratpack

ratpack {
  bindings {
    module(HikariModule) { config ->
      config.dataSourceClassName = 'org.h2.jdbcx.JdbcDataSource'
      config.addDataSourceProperty('URL', "jdbc:h2:mem:tood;INIT=RUNSCRIPT FROM
'classpath:/init.sql'")
    }
    module(TodoModule)
  }
  handlers {
    all(new CORSHandler())
    get('blocking') { TodoRepository repository ->
      repository.getAll()
        .map(Jackson.&json)
        .then(context.&render)
    }
  }
}
```

10. Working with JSON

Now that we have our datasource and `TodoRepository` it's time to implement the various `Handler` s for interfacing with the `TodoRepository`.

10.1. Parsing JSON

Ratpack has a parsing framework that understands how to parse incoming JSON to Pojos. The `Context#parse` returns a `Promise` which will then provide the parsed JSON object.

example-06-json/src/ratpack/ratpack.groovy

```
post {
  Promise<TodoModel> todo = parse(Jackson.fromJson(TodoModel)) ①
  todo.then { t -> render t.title } ②
}
```

① We make use of `Jackson.fromJson` to specify our desired type

② Once the promise is resolved we render the parsed title back to the user

Let's take a look at this JSON title rendering in action.

ratpack Demo

```
$ ./gradlew :example-06-json:run ①

$ curl -X POST -H 'Content-type: application/json' --data '{"title":"New Task"}'
http://localhost:5050/
New Task

$ curl -X POST -H 'Content-type: application/json' --data '{"title":"Attend Greach
2017"}' http://localhost:5050/
Attend Greach 2017
```

10.2. Integrating with TodoRepository

Now that we see how easy it to parse incoming JSON, we'll now update the `Handler` to persist this JSON payload.

example-06-json/src/ratpack/ratpack2.groovy

```
post { TodoRepository repository -> ①
  Promise<TodoModel> todo = parse(Jackson.fromJson(TodoModel)) ②
  todo
    .flatMap(repository.&add) ③
    .map(Jackson.&json) ④
    .then(context.&render) ⑤
}
```

① Retrieve `TodoRepository` from `Context` registry

② Parse incoming JSON payload

③ Add parsed JSON to repository

④ Map the resulting `TodoModel` as a renderable JSON object

⑤ Render the response to the client

ratpack2 Demo

```
$ curl -X POST -H 'Content-type: application/json' --data '{"title":"New Task"}'
http://localhost:5050/
{"id":1,"title":"New Task","completed":false,"order":null,"url":"null/1"}

$ curl -X POST -H 'Content-type: application/json' --data '{"title":"Attend Greach
2017"}' http://localhost:5050/
{"id":2,"title":"Attend Greach 2017","completed":false,"order":null,"url":"null/2"}

$ curl http://localhost:5050/blocking
[{"id":1,"title":"New
Task","completed":false,"order":null,"url":"null/1"},{"id":2,"title":"Attend Greach
2017","completed":false,"order":null,"url":"null/2"}]
```

10.3. Reading and Writing

Now that we've implemented the `POST /` endpoint for persisting Todo items, let's put it together with `GET /`. You may be tempted to write your chain in this way:

example-06-json/src/ratpack/ratpack3.groovy

```
get { TodoRepository repository ->
  repository.getAll()
    .map(Jackson.&json)
    .then(context.&render)
}
post { TodoRepository repository ->
  Promise<TodoModel> todo = parse(Jackson.fromJson(TodoModel))
  todo
    .flatMap(repository.&add)
    .map(Jackson.&json)
    .then(context.&render)
}
```

However you'll run into some strange behavior:

ratpack3 Demo

```
$ curl http://localhost:5050/
[]

$ curl -X POST -H 'Content-type: application/json' --data '{"title":"Attend Greach
2017"}' --raw -v -s http://localhost:5050/
* timeout on name lookup is not supported
*   Trying ::1...
* Connected to localhost (::1) port 5050 (#0)
> POST / HTTP/1.1
> Host: localhost:5050
> User-Agent: curl/7.45.0
> Accept: */*
> Content-type: application/json
> Content-Length: 31
>
* upload completely sent off: 31 out of 31 bytes
< HTTP/1.1 405 Method Not Allowed ①
< content-length: 0
< connection: close
<
```

① Method not Allowed?!?!

10.4. ByMethodSpec

The way the `Chain` works is to eagerly match against incoming request path and then the HTTP method. Because we declared `get(Handler)` before `post(Handler)`, Ratpack will stop looking for handlers after it finds `get(Handler)` since we've matched the request path. The way to provide multiple methods for the same path is to use `Chain#path` and `Context#byMethod`.

example-06-json/src/ratpack/ratpack4.groovy

```
path { TodoRepository repository ->  ① ②
  byMethod { ③
    get { ④
      repository.getAll()
        .map(Jackson.&json)
        .then(context.&render)
    }
    post { ⑤
      Promise<TodoModel> todo = parse(Jackson.fromJson(TodoModel))
      todo
        .flatMap(repository.&add)
        .map(Jackson.&json)
        .then(context.&render)
    }
  }
}
```

① Use `Chain#path` to match on path without HTTP method

② Retrieve `TodoRepository` from `Context`

③ Use `Context#byMethod` to specify which HTTP methods are considered as valid methods for this path

④ Move previous `Chain#get` handler to the `ByMethodSpec#get` block

⑤ Move previous `Chain#post` handler to the `ByMethodSpec#post` block

Now that we're using `Context#byMethod` let's check our results:

ratpack4 Demo

```
$ curl http://localhost:5050/
[]

$ curl -X POST -H 'Content-type: application/json' --data '{"title":"Attend Greach
2017"}' http://localhost:5050/
{"id":1,"title":"Attend Greach 2017","completed":false,"order":null,"url":"null/1"}

$ curl http://localhost:5050/
[{"id":1,"title":"Attend Greach 2017","completed":false,"order":null,"url":"null/1"}]
```

10.5. Putting it all together

We will now combine the CORSHandler with all of the endpoints for performing REST CRUD operations.

example-06-json/src/ratpack/ratpack5.groovy

```
import ratpack.hikari.HikariModule
import ratpack.jackson.Jackson
import ratpack.exec.Promise

import static ratpack.groovy.Groovy.ratpack

ratpack {
  bindings {
    module(HikariModule) { config ->
      config.dataSourceClassName = 'org.h2.jdbcx.JdbcDataSource'
      config.addDataSourceProperty('URL', "jdbc:h2:mem:tood;INIT=RUNSCRIPT FROM
'classpath:/init.sql'")
    }
    module(TodoModule)
    bindInstance(new CORSHandler()) ①
  }
  handlers {
    all(CORSHandler) ②
    path { TodoRepository repository -> ③
      byMethod {
        options {
          response.headers.set('Access-Control-Allow-Methods', 'OPTIONS, GET, POST,
DELETE')
          response.send()
        }
        get {
          repository.getAll()
            .map(Jackson.&json)
            .then(context.&render)
        }
        post {
          Promise<TodoModel> todo = parse(Jackson.fromJson(TodoModel))
          todo
            .flatMap(repository.&add)
            .map(Jackson.&json)
            .then(context.&render)
        }
        delete {
          repository.deleteAll().then(response.&send)
        }
      }
    }
  }
}
```

① Add our `CORSHandler` back into the registry

② Ensure that all requests to go through `CORSHandler`

③ Setup logic for REST CRUD operations

```
$ curl http://localhost:5050/
[]

$ curl -X OPTIONS --raw -v -s http://localhost:5050/
* timeout on name lookup is not supported
*   Trying ::1...
* Connected to localhost (::1) port 5050 (#0)
> OPTIONS / HTTP/1.1
> Host: localhost:5050
> User-Agent: curl/7.45.0
> Accept: */*
>
< HTTP/1.1 200 OK
< Access-Control-Allow-Origin: *
< Access-Control-Allow-Headers: x-requested-with, origin, content-type, accept
< Access-Control-Allow-Methods: OPTIONS, GET, POST, DELETE
< content-length: 0
< connection: keep-alive
<

$ curl -X POST -H 'Content-type: application/json' --data '{"title":"Attend Greach
2017"}' http://localhost:5050/
{"id":1,"title":"Attend Greach 2017","completed":false,"order":null,"url":"null/1"}

$ curl http://localhost:5050/
[{"id":1,"title":"Attend Greach 2017","completed":false,"order":null,"url":"null/1"}]

$ curl -X DELETE http://localhost:5050/

$ curl http://localhost:5050/
[]
```

11. Evolution

As your codebase grows, so will your chains. Ratpack has several mechanisms for composing chains that help maintain readability.

11.1. Action<Chain>

Ratpack allows you to insert `Action<Chain>` s to the chain, which allows for basic composition.

In the following example we will take our chain and migrate it to a class that implements `Action<Chain>`. We'll also take this opportunity to leverage Ratpack's `InjectionHandler`. Up until this point we have been using Ratpack's handler type that allows declaration of registered objects as parameters in closures. Ratpack provides a type of `Handler` that declares your registry objects by type to facilitate registry retrieval.

example-07-evolution/src/main/groovy/TodoBaseHandler.groovy

```
import groovy.transform.CompileStatic
import ratpack.exec.Promise
import ratpack.func.Action
import ratpack.handling.ByMethodSpec
import ratpack.handling.Context
import ratpack.handling.InjectionHandler
import ratpack.http.Response
import ratpack.jackson.Jackson

@CompileStatic
class TodoBaseHandler extends InjectionHandler { ①
  void handle(Context ctx, TodoRepository repository) throws Exception { ②
    Response response = ctx.response
    ctx.byMethod({ ByMethodSpec method -> method
      .options {
        response.headers.set('Access-Control-Allow-Methods', 'OPTIONS, GET, POST,
DELETE')
        response.send()
      }
      .get {
        repository.all
          .map(Jackson.&json)
          .then(ctx.&render)
      }
      .post {
        Promise<TodoModel> todo = ctx.parse(Jackson.fromJson(TodoModel))
        todo
          .flatMap(repository.&add)
          .map(Jackson.&json)
          .then(ctx.&render)
      }
      .delete { repository.deleteAll().then(response.&send) }
    } as Action<ByMethodSpec>)
  }
}
```

① Extend `InjectionHandler`

② Provide a `void handle()` method that has our types of interest, in this case we want the `TodoRepository`

We now create an instance of `Action<Chain>` that represents everything about REST CRUD interactions with Todo objects.

example-07-evolution/src/main/groovy/TodoChain.groovy

```
import ratpack.groovy.handling.GroovyChainAction

class TodoChain extends GroovyChainAction {
  @Override
  void execute() throws Exception {
    path(TodoBaseHandler)
  }
}
```

Once this is complete we can come back to the main application and update accordingly.

example-07-evolution/src/ratpack/ratpack.groovy

```
import ratpack.hikari.HikariModule

import static ratpack.groovy.Groovy.ratpack

ratpack {
  bindings {
    module(HikariModule) { config ->
      config.dataSourceClassName = 'org.h2.jdbcx.JdbcDataSource'
      config.addDataSourceProperty('URL', "jdbc:h2:mem:tood;INIT=RUNSCRIPT FROM
'classpath:/init.sql'")
    }
    module(TodoModule)
    bindInstance(new CORSHandler())
    bindInstance(new TodoBaseHandler()) ①
    bindInstance(new TodoChain()) ②
  }
  handlers {
    all(CORSHandler)
    insert(TodoChain) ③
  }
}
```

① Register our new `TodoBaseHandler`

② Register our new `TodoChain`

③ Insert our `GroovyChainAction` that we have registered

All of the previous REST CRUD functionality is preserved.

11.2. Implementing Individual Todo chain

We want to provide the ability to perform CRUD operations on an individual Todo basis. We'll make use of the `TodoChain` and `InjectionHandler` once again to provide this REST CRUD functionality. This individual `TodoHandler` will handle REST CRUD functionality on a per Todo basis.

example-07-evolution/src/main/groovy/TodoHandler.groovy

```
import com.google.common.reflect.TypeToken
import groovy.transform.CompileStatic
import ratpack.exec.Promise
import ratpack.func.Action
import ratpack.func.Function
import ratpack.handling.ByMethodSpec
import ratpack.handling.Context
import ratpack.handling.InjectionHandler
import ratpack.http.Response
import ratpack.jackson.Jackson
import ratpack.jackson.JsonRender

@CompileStatic
class TodoHandler extends InjectionHandler {
  void handle(Context ctx, TodoRepository repo, String base) throws Exception {
    Long todoId = Long.parseLong(ctx.pathTokens.get('id'))

    Function<TodoModel, TodoModel> hostUpdater = { TodoModel todo -> todo.baseUrl(
base) } as Function<TodoModel, TodoModel>
    Function<TodoModel, JsonRender> toJson = hostUpdater.andThen { todo -> Jackson
.json(todo) }

    Response response = ctx.response

    ctx.byMethod({ ByMethodSpec byMethodSpec -> byMethodSpec
      .options {
        response.headers.set('Access-Control-Allow-Methods', 'OPTIONS, GET, PATCH,
DELETE')
        response.send()
      }
      .get { repo.getById(todoId).map(toJson).then(ctx.&render) }
      .patch {
        ctx
          .parse(Jackson.fromJson(new TypeToken<Map<String, Object>>() {}))
          .map({ Map<String, Object> map ->
            Map<String, Object> patch = map.keySet().inject([:]) { m, key ->
              m[key.toUpperCase()] = map[key]
              return m
            } as Map<String, Object>
            patch['ID'] = todoId
            return patch
          } as Function<Map<String, Object>, Map<String, Object>>)
          .flatMap(repo.&update as Function<Map<String, Object>, Promise<TodoModel>>)
          .map(toJson)
          .then(ctx.&render)
      }
      .delete { repo.delete(todoId).then(response.&send) }
    } as Action<ByMethodSpec>)
  }
```

```
}
```

After implementing the `TodoHandler` we'll need to add it to the registry and to the `TodoChain`.

example-07-evolution/src/main/groovy/TodoChain2.groovy

```
import ratpack.groovy.handling.GroovyChainAction

class TodoChain2 extends GroovyChainAction {
  @Override
  void execute() throws Exception {
    path(TodoBaseHandler2)
    path(':id', TodoHandler) ①
  }
}
```

① Making use of `PathTokens` to extract dynamic `id` parameter from path and assigning our `TodoHandler` to handle this path

To finish this implementation we'll the handler to the registry.

example-07-evolution/src/ratpack/ratpack2.groovy

```
bindInstance(new TodoHandler()) ①
```

11.3. Putting it all together

We're adding `String` to the registry which represents base url of the REST api

example-07-evolution/src/main/groovy/CORSHandler.groovy

```
import groovy.transform.CompileStatic
import ratpack.groovy.handling.GroovyContext
import ratpack.groovy.handling.GroovyHandler
import ratpack.http.MutableHeaders
import ratpack.registry.Registry

@CompileStatic
class CORSHandler extends GroovyHandler {
  @Override
  protected void handle(GroovyContext context) {
    MutableHeaders headers = context.response.headers
    headers.set('Access-Control-Allow-Origin', '*')
    headers.set('Access-Control-Allow-Headers', 'x-requested-with, origin, content-
type, accept')
    String host = context.request.headers.get('HOST')
    String baseUrl = "http://$host" ①
    context.next(Registry.single(String, baseUrl)) ②
  }
}
```

① Create a base url

② Add base url to the registry

```
$ curl http://localhost:5050/
[]

$ curl -X POST -H 'Content-type: application/json' --data '{"title":"Attend Greach
2017"}' http://localhost:5050/
{"id":1,"title":"Attend Greach
2017","completed":false,"order":null,"url":"http://localhost:5050/1"}

$ curl http://localhost:5050/
[{"id":1,"title":"Attend Greach
2017","completed":false,"order":null,"url":"http://localhost:5050/1"}]

$ curl http://localhost:5050/1
{"id":1,"title":"Attend Greach
2017","completed":false,"order":null,"url":"http://localhost:5050/1"}

$ curl -X PATCH -H 'Content-type: application/json' --data '{"completed": true}'
http://localhost:5050/1
{"id":1,"title":"Attend Greach
2017","completed":true,"order":null,"url":"http://localhost:5050/1"}

$ curl http://localhost:5050/
[{"id":1,"title":"Attend Greach
2017","completed":true,"order":null,"url":"http://localhost:5050/1"}]

$ curl -X DELETE http://localhost:5050/1

$ curl http://localhost:5050/
[]

$ curl http://localhost:5050/1
```

12. Deploying to Heroku

Heroku is PaaS that allows you to deploy you applications quickly. It's a great way to "get something" out there while quickly iterating. You can prototype for free and once you're ready to "go live" you can pay for your usage.

To get started you'll need:

- A Heroku account (no credit card required)
- Heroku toolbelt — command line binaries for working with Heroku

12.1. Setup

In order to deploy our application to Heroku we'll need two pieces of information:

- A `Procfile`
- A `stage` task when using Gradle

Let's go over the changes we'll need to make to the Gradle build script.

example-08-heroku/example-08-heroku.gradle

```
plugins {
  id 'io.ratpack.ratpack-groovy' version '1.4.5'
  id 'com.github.johnrengelman.shadow' version '1.2.4' ①
}

task stage(dependsOn: installShadowApp) ②
```

① I recommend using Shadow plugin for packaging your Java applications for production

② We create a `stage` task that invokes `installShadowApp`

The second change we need to make is to add a file called `Procfile`. This file is a signal that communicates to Heroku what command to invoke to start our application.

example-08-heroku/Procfile

```
web: build/installShadow/example-08-heroku/bin/example-08-heroku
```

12.2. Creating and deploying the application to Heroku

```
$ heroku apps:create todo-backend-ratpack-groovy ①
Creating todo-backend-ratpack-groovy... done, stack is cedar-14
https://todo-backend-ratpack-groovy.herokuapp.com/ | https://git.heroku.com/todo-
backend-ratpack-groovy.git

$ heroku git:remote --app todo-backend-ratpack-groovy ②
set git remote heroku to https://git.heroku.com/todo-backend-ratpack-groovy.git

$ git remote -v ③
heroku  https://git.heroku.com/todo-backend-ratpack-groovy.git (fetch)
heroku  https://git.heroku.com/todo-backend-ratpack-groovy.git (push)

$ git push heroku master ④

$ heroku logs -t ⑤

$ curl https://todo-backend-ratpack-groovy.herokuapp.com/todo ⑥
[]
```

① Create a new application (Heroku will assign a random name if you don't)

② Add heroku git repository to our remotes

③ View urls for the newly added git remote

④ Push our code to the newly minted heroku remote repository

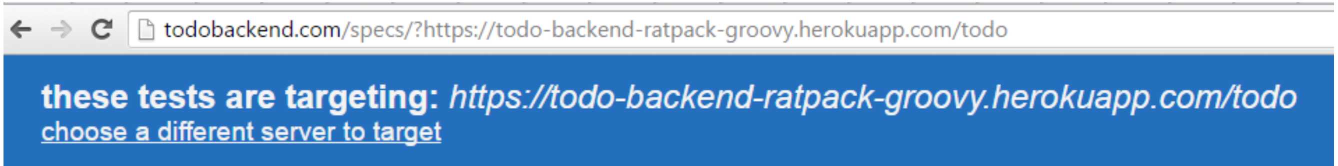
⑤ Tail your application logs

⑥ Curl against your application in the wild!

12.3. Final Product

With our application deployed and serving traffic, let's finish by running the TodoBackend specifications against our application.

You can navigate to the specification page to see the tests in action: http://todobackend.com/specs/?https://todo-backend-ratpack-groovy.herokuapp.com/todo



passes: 16 failures: 0 duration: 6.33s

Todo-Backend API residing at https://todo-backend-ratpack-groovy.herokuapp.com/todo

the pre-requisites

- ✓ the api root responds to a GET (i.e. the server is up and accessible, CORS headers are set up)
- ✓ the api root responds to a POST with the todo which was posted to it
- ✓ the api root responds successfully to a DELETE
- ✓ after a DELETE the api root responds to a GET with a JSON representation of an empty array

storing new todos by posting to the root url

- ✓ adds a new todo to the list of todos at the root url
- ✓ sets up a new todo as initially not completed
- ✓ each new todo has a url
- ✓ each new todo has a url, which returns a todo

working with an existing todo

- ✓ can navigate from a list of todos to an individual todo via urls
- ✓ can change the todo's title by PATCHing to the todo's url
- ✓ can change the todo's completedness by PATCHing to the todo's url
